Abstract

Deep neural networks are highly expressive models that have recently achieved state of the art performance on speech and visual recognition tasks. While their expressiveness is the reason they succeed, it also causes them to learn uninterpretable solutions that could have counter-intuitive properties. In this paper we report two such properties.

First, we find that there is no distinction between individual high level units and random linear combinations of high level units, according to various methods of unit analysis. It suggests that it is the space, rather than the individual units, that contains the semantic information in the high layers of neural networks.

Second, we find that deep neural networks learn input-output mappings that are fairly discontinuous to a significant extent. We can cause the network to misclassify an image by applying a certain hardly perceptible perturbation, which is found by maximizing the network's prediction error. In addition, the specific nature of these perturbations is not a random artifact of learning: the same perturbation can cause a different network, that was trained on a different subset of the dataset, to misclassify the same input.

One of 35 papers, presented at the
2nd International Conference on
Learning Representations (ICLR),
held in 2014

Adversarial Examples

The second property is concerned with the stability of neural networks with respect to small perturbations to their inputs. Consider a state-of-the-art deep neural network that generalizes well on an object recognition task. We expect such network to be robust to small perturbations of its input, because small perturbation cannot change the object category of an image. However, we find that applying an *imperceptible* non-random perturbation to a test image, it is possible to arbitrarily change the network's prediction (see figure 5). These perturbations are found by optimizing the input to maximize the prediction error. We term the so perturbed examples “adversarial examples”.

$$x_{adv} = x + \delta \quad \text{s.t.} \quad \|\delta\| \leq \epsilon$$

Adversarial perturbation

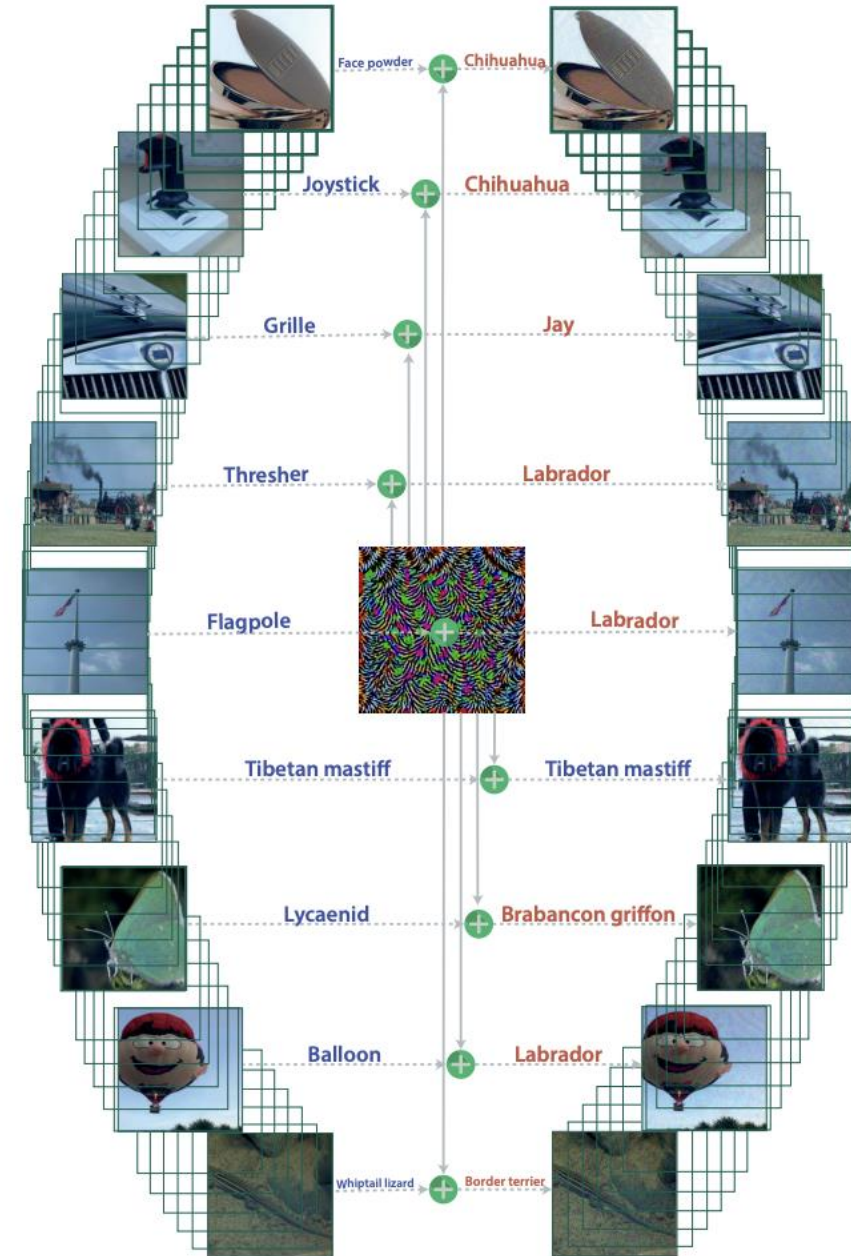

Why “Intriguing”?

- The adversarial perturbation is “imperceptible”.
 - Adversarial examples with a larger perturbation provides trivial results.
 - The maximum perturbation value: e.g., $\frac{8}{255} \approx 0.03$
- The adversarial examples are transferable.

Why “Intriguing”?

- There exists one adversarial perturbation that makes the most images being misclassified

Contents

- Is it practical?

Generating Adversarial Examples

High-level Objective

$$\max_{\delta \in S} \ell(f, x + \delta, y)$$

- (x, y) : a labeled example
- f : a classifier
- $\ell(f, x, y)$: loss
- S : a set of perturbations
- $x + \delta$: an adversarial example that is misclassified by f

FGSM: Fast Gradient Sign Method

THE LINEAR EXPLANATION OF ADVERSARIAL EXAMPLES

ABSTRACT

Several machine learning models, including neural networks, consistently misclassify *adversarial examples*—inputs formed by applying small but intentionally worst-case perturbations to examples from the dataset, such that the perturbed input results in the model outputting an incorrect answer with high confidence. Early attempts at explaining this phenomenon focused on nonlinearity and overfitting. We argue instead that the primary cause of neural networks’ vulnerability to adversarial perturbation is their linear nature. This explanation is supported by new quantitative results while giving the first explanation of the most intriguing fact about them: their generalization across architectures and training sets. Moreover, this view yields a simple and fast method of generating adversarial examples. Using this approach to provide examples for adversarial training, we reduce the test set error of a maxout network on the MNIST dataset.

FGSM

- Objective:

$$\max_{\delta: \|\delta\|_{\infty} \leq \epsilon} \ell(f, x + \delta, y)$$

- Solution:

$$\delta = \epsilon \cdot \text{sign}(\nabla_x \ell(f, x, y))$$

- Intuition: Linearize the loss function around the parameter f .

FGSM: Optimality Analysis

- Taylor expansion of a function $f(x)$ at a :

$$f(x) \approx f(a) + \frac{f'(a)}{1!} (x - a) + \frac{f''(a)}{2!} (x - a)^2 + \dots$$

- The first order Taylor expansion of loss at an example x :

$$\ell(f, x + \delta, y) =: \ell'(x + \delta) \approx \ell'(x) + \nabla \ell'(x)^T \delta$$

FGSM: Optimality Analysis

- The first order Taylor expansion of loss at an example x_0 :

$$\ell(f, x + \delta, y) =: \ell'(x + \delta) \approx \ell'(x) + \nabla \ell'(x)^T \delta$$

- We have

$$\max_{\delta: \|\delta\|_\infty \leq \epsilon} \ell(f, x + \delta, y) \approx \max_{\delta: \|\delta\|_\infty \leq \epsilon} \ell(x) + \nabla \ell(x)^T \delta$$

- Clearly linear in δ
 - Use the standard Lagrange multiplier method
- Solution:

$$\delta = \epsilon \cdot \text{sign}(\nabla \ell(x))$$

FGSM Results

Error: 1.6%

Error: 99%
(FGSM with $\epsilon = 0.25$)

- Results with a linear model
 - FGSM generates (almost) optimal perturbations.

General Framework

Gradient regularization family (1/2)

$$\delta = \epsilon \cdot \text{sign}(\nabla_x \ell(f, x, y)) \left(\frac{\nabla_x \ell(f, x, y)}{\|\nabla_x \ell(f, x, y)\|_{p^*}} \right)^{\frac{1}{p-1}}$$

- p^* is the dual of p , i.e., $\frac{1}{p^*} + \frac{1}{p} = 1$.

General Framework

Gradient regularization family (2/2)

$$\begin{aligned} & \lim_{p \rightarrow \infty} \epsilon \cdot \text{sign}(\nabla_x \ell(f, x, y)) \left(\frac{\nabla_x \ell(f, x, y)}{\|\nabla_x \ell(f, x, y)\|_{p^*}} \right)^{\frac{1}{p-1}} \\ &= \epsilon \cdot \text{sign}(\nabla_x \ell(f, x, y)) \left(\frac{\nabla_x \ell(f, x, y)}{\|\nabla_x \ell(f, x, y)\|_1} \right)^0 \\ &= \epsilon \cdot \text{sign}(\nabla_x \ell(f, x, y)) \end{aligned}$$

What's the Cause of Adversarial Examples?

*Adversarial vulnerability is a direct result of sensitivity to **well-generalizing features** in the data.*

Abstract

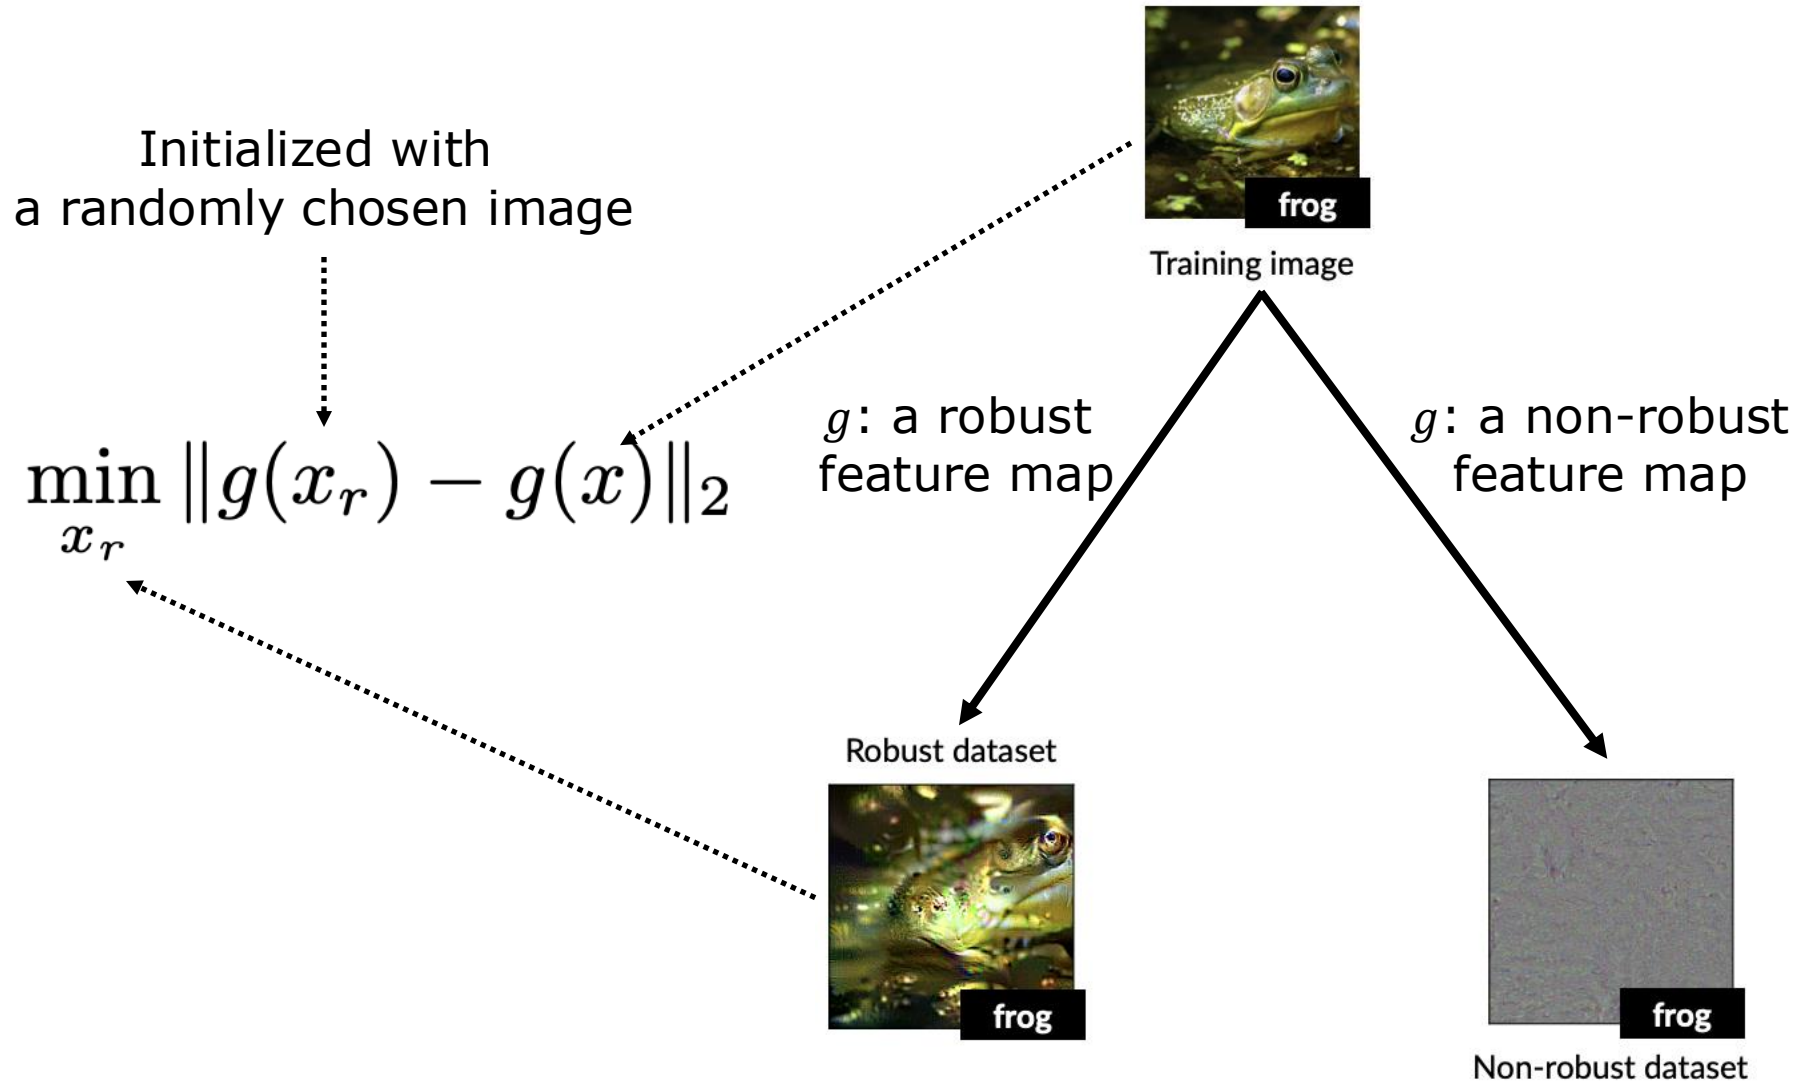

Adversarial examples have attracted significant attention in machine learning, but the reasons for their existence and pervasiveness remain unclear. We demonstrate that adversarial examples can be directly attributed to the presence of *non-robust features*: features (derived from patterns in the data distribution) that are highly predictive, yet brittle and (thus) incomprehensible to humans. After capturing these features within a theoretical framework, we establish their widespread existence in standard datasets. Finally, we present a simple setting where we can rigorously tie the phenomena we observe in practice to a *misalignment* between the (human-specified) notion of robustness and the inherent geometry of the data.

Experiment Setup

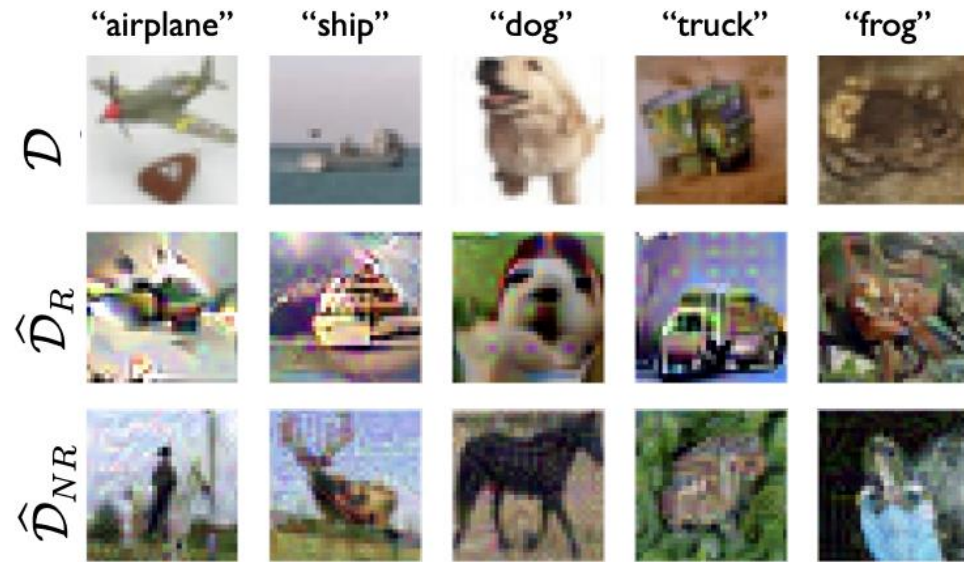

Claim: There are two features: (1) robust features and (2) non-robust features; the non-robust features contribute to adversarial examples!

How to Construct Datasets

Results

- The standard model picks (noisy-looking) non-robust features to classify images; thus, it is susceptible to adversarial perturbations.

Wait! Practical?

How can an attacker inject an adversarial example in practice?

Adversarial Patch

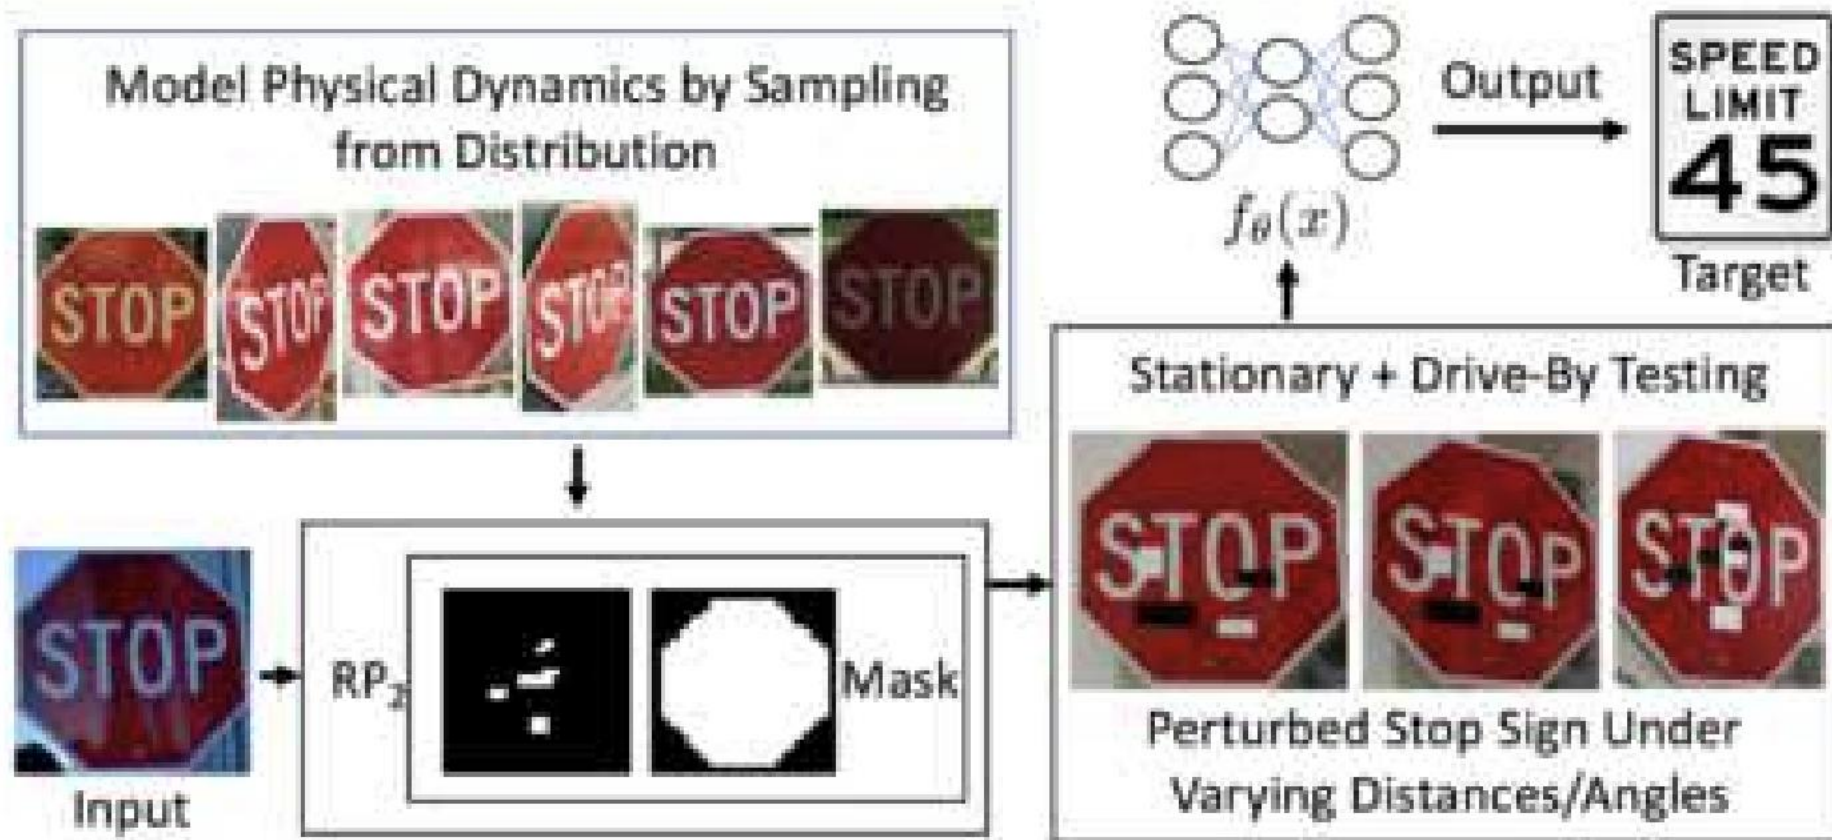

Adversarial Patch (NIPS17 Workshop)

Adversarial Patch for Object Detectors

Physical Adversarial Examples

Black-Box Attacks

- What if we don't have a target model?

$$\min_{\delta} \ell_y(\mathbf{x} + \delta) \text{ subject to: } \|\delta\|_2 < \rho, \text{ queries} \leq B$$

Algorithm 1 SimBA in Pseudocode

```
1: procedure SIMBA( $\mathbf{x}, y, Q, \epsilon$ )
2:    $\delta = \mathbf{0}$ 
3:    $\mathbf{p} = p_h(y \mid \mathbf{x})$ 
4:   while  $\mathbf{p}_y = \max_{y'} \mathbf{p}_{y'}$  do
5:     Pick randomly without replacement:  $\mathbf{q} \in Q$ 
6:     for  $\alpha \in \{\epsilon, -\epsilon\}$  do
7:        $\mathbf{p}' = p_h(y \mid \mathbf{x} + \delta + \alpha \mathbf{q})$ 
8:       if  $\mathbf{p}'_y < \mathbf{p}_y$  then
9:          $\delta = \delta + \alpha \mathbf{q}$ 
10:         $\mathbf{p} = \mathbf{p}'$ 
11:        break
   return  $\delta$ 
```

Observation: random noise in low frequency space is more likely to be adversarial

Conclusion

- Small adversarial perturbations degrade the performance of predictors.
- Adversarial perturbations are realizable.
 - Physical adversarial examples
 - Eyeglass
 - Adversarial patch
- Even without complete knowledge on a model, we can generate adversarial perturbations.
- How can we learn a neural network that is robust to adversarial perturbations *with guarantees*?
